Solar System Overview

Overview

The Solar System consists of the Sun and the objects that orbit it. The name comes from Sōl, the Latin name for the Sun. It formed when a dense region of a collapsed, rotating cloud of gas and dust, creating the Sun and a disk from which the orbiting bodies assembled. The Sun's fusion of hydrogen into helium inside the core releases energy, which is primarily emitted as light and heat.

What are the different types of planets in our solar system?

There are 17 different types of planets on the basis of composition. Helium Planet. Gas Giant. Gas Dwarf. Desert Planet. Coreless Planet. City Planet. Carbon Planet. Chthonian Planet. How many planets are there in the universe in the universe?

How many planets are in our solar system?

First the quick facts: Our Solar System has eight “official” planets which orbit the Sun. Here are the planets listed in order of their distance from the Sun: Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, and Neptune. An easy mnemonic for remembering the order is “My Very Educated Mother Just Served Us Noodles.”.

What is beyond our solar system?

The planets beyond our solar system are called “exoplanets,” and they come in a wide variety of sizes, from gas giants larger than Jupiter to small, rocky planets about as big around as Earth or Mars. They can be hot enough to boil metal or locked in deep freeze.

What is NASA's role in exploring the solar system?

Water is just one piece of our search for habitable planets and life beyond Earth, yet it links many seemingly unrelated worlds in surprising ways. NASA is looking to answer key questions about our home planet, neighboring planets in our solar system and the universe beyond: How did our solar system originate and change over time?
